Problem 10: Busiest Bus Row

TASK

A college bus records how many students sit in each seat as a 2D grid, where each row is one row of seats. The transport office wants to know which row carries the most students.

Implement a function `busiestRow(grid)` that returns the index of the row with the largest total and that total. If two rows tie, return the one with the smaller index.

CONSTRAINTS

- 1 <= rows, columns <= 10
- 0 <= grid[i][j] <= 3

EXAMPLE

```
grid = [[2, 0, 1],
        [3, 3, 1],
        [1, 1, 1]]

Expected Output: Row 1, Total 7
```

COMPLEXITY REQUIREMENTS

State the time complexity in terms of r (rows) and c (columns), and the additional space used.

HINT

> *Use an outer loop for the rows and an inner loop to add up the seats in each row; update the best row only when a total is strictly larger.*
